Abstract

We study $\mu - e$ conversion with sequential four generations. A large mass for the fourth generation neutrino can enhance the conversion rate by orders of magnitude. We compare constraints obtained from $\mu - e$ conversion using experimental bounds on various nuclei with those from $\mu \to e\gamma$ and $\mu \to e\bar{e}e$. We find that the current bound from $\mu - e$ conversion with Au puts the most stringent constraint in this model. The relevant flavor changing parameter $\lambda_{\mu e} = V^*_{\mu 4} V_{e4}$ is constrained to be less than 1.6×10^{-5} for the fourth generation neutrino mass larger than 100 GeV. Implications for future $\mu - e$ conversion, $\mu \to e\gamma$ and $\mu \to e\bar{e}e$ experiments are discussed.

I. INTRODUCTION

The standard model (SM) of electroweak and strong interactions based on the gauge group $SU(3)_C \times SU(2)_L \times U(1)_Y$ has been rigorously tested in many ways[1], in different sectors involving gauge bosons, quarks and leptons. The flavor physics in the quark sector including CP violation is well described by the Cabibbo-Kobayashi-Maskawa (CKM) mixing matrix[2, 3] in the charged current interactions of the W boson with three generations of quarks. Corresponding interactions in the leptonic sector are not on the same footing. In the simplest version of the SM, there are no right handed neutrinos, and the left handed neutrinos are massless. This theory conserves lepton flavor of each family separately, and no flavor changing neutral current (FCNC) processes are allowed in the leptonic sector. However, the observation of neutrino oscillations requires both a non-zero neutrino mass and lepton flavor violation (LFV). The SM has to be extended to give neutrino masses and explain their mixing through a mixing matrix in the charged currents analogous to the CKM matrix in the quark sector, the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) mixing matrix[4, 5]. There are many ways to extend the SM to have neutrino masses and mixing, for example, introduction of right-handed neutrinos to have Dirac mass, or to invoke seesaw mechanism to have Majorana mass, or to have loop induced masses. The existence of mixing among different lepton generations will induce FCNC interactions with LFV. To further understand the properties of the underlying theory, one should not only study whether a model can produce the correct neutrino masses and their mixing, it is also necessary to study possible implications for other FCNC interaction and confront them with existing and future experimental data. A particularly interesting process is $\mu - e$ conversion.

$\mu - e$ conversion has been studied both theoretically and experimentally [6–9]. The quantity measuring the strength of this leptonic FCNC process is $B^A_{\mu\to e} = \Gamma^A_{conv}/\Gamma^A_{capt} = \Gamma(\mu^- + A(N,Z) \to e^- + A(N,Z))/\Gamma(\mu^- + A(N,Z) \to \nu_\mu + A(N+1, Z-1)$. Experimental bounds on $\mu - e$ conversion for several nuclei have been obtained as $B^{\mathrm{Au}}_{\mu\to e} < 7 \times 10^{-13}$[10], $B^{\mathrm{S}}_{\mu\to e} < 7 \times 10^{-11}$[11], $B^{\mathrm{Ti}}_{\mu\to e} < 4.3 \times 10^{-12}$[12] and $B^{\mathrm{Pb}}_{\mu\to e} < 4.6 \times 10^{-11}$[13] with the 90% c.f. level. These limits can give important information for leptonic FCNC interactions.

There are many different ways to extend the SM to have neutrino masses and mixing, and therefore leptonic FCNC interactions. In this work, we study implications on $\mu - e$ conversion, in one of the simplest extension of the SM by introducing right-handed neutrinos to have Dirac masses. In this model, $\mu - e$ conversion cannot occur at tree level. At one loop level, it can be induced by the photon and Z penguin, and box diagrams. Since the Glashow-Iliopoulos-Maiani(GIM) mechanism is in effect, all leptonic FCNC processes involving charged leptons are proportional to $m^2_{\nu_i}/m^2_W$, here m_ν is the neutrino mass and m_W is the W boson mass. In the SM with three generations (SM3), due to the very tiny neutrino masses ($\lesssim 0.2$ eV), all LFV rates are extremely small. If the model is further extended to have a fourth generation (SM4), and if the fourth generation neutrino mass m_{ν_4} is large enough, the factor $m^2_{\nu_i}/m^2_W$ can even become an enhancement factor, and therefore can have observable leptonic FCNC effects. In other words, the current experimental bounds can be used to constrain model parameters. FCNC interaction with SM4 has been studied for a long time[14] and can also help for solving some of open questions in FCNC quark interaction[15]. Leptonic FCNC effects, including $\mu - e$ conversion, in SM4 have also been studied extensively[16–19]. In our work we carry out a more detailed systematic study by taking account of all available $\mu - e$ conversion experimental results. We compare constraints obtained from $\mu - e$ conversion using experimental bounds on various nuclei with those from $\mu \to e\gamma$ and $\mu \to e\bar{e}e$. We find that the current bound from $\mu - e$ conversion with Au puts the most stringent constraints on model parameters. The relevant flavor changing parameter $\lambda_{\mu e} = V^*_{\mu 4} V_{e4}$ is constrained to be less than 1.6×10^{-5} for m_{ν_4} larger than 100 GeV. Future improved experiments on $\mu - e$ conversion, $\mu \to e\gamma$ and $\mu \to e\bar{e}e$ will further constrain model parameters.

II. THE FCNC INTERACTIONS FOR $\mu - e$ CONVERSION IN SM4

The minimal set of particle contents in the SM is the gauge bosons of the gauge group $SU(3)_C \times SU(2)_L \times U(1)_Y$ with couplings g_s, g and g', the Higgs doublet $\Phi : (1, 2, +1)$ with the component fields and vacuum expectation value (vev) $v = \langle h \rangle$ given by $\Phi = (\omega^+, (v+h+iz)/\sqrt{2})^T$, the three generations of left and right handed up and down quarks, $Q_L : (3, 2, 1/3)$, $U_R : (3, 1, 4/3)$, $D_R : (3, 1, -2/3)$, and the three generations of left handed leptons $L_L : (1, 2, -1)$ and right handed charged leptons, $E_R : (1, 1, -2)$. We use the hypercharge normalization that $Q = I_3 + Y/2$. Depending on the nature of the neutrinos, there may be right handed neutrinos, $N_R : (1, 1, 0)$ which may pair up with the left handed neutrinos to have Dirac or by themselves to have Majorana masses.

For a model with Dirac neutrino mass only, the charged lepton and neutrino masses are generated by the Yukawa interactions

$$L = -\bar{L}_L Y_E \Phi E_R - \bar{L}_L Y_N \tilde{\Phi} N_R + h.c. \tag{1}$$

where $\tilde{\Phi} = i\sigma_2 \Phi^*$, $E_R = (e, \mu, \tau, ...)^T_R$, $N_R = (\nu_e, \nu_\mu, \nu_\tau, ...)^T_R$ for n generations of leptons. Y_E and Y_ν are $n \times n$ matrices.

After the Higgs boson develops a non-zero vev, the leptons will obtain their masses with the mass matrices for charged leptons and neutrinos which are given by

$$M_E = Y_E \frac{v}{\sqrt{2}} \ , \ \ M_\nu = Y_N \frac{v}{\sqrt{2}} \ . \tag{2}$$

In the basis where the mass matrices are all diagonal, the flavor changing interactions involving leptons are contained in the PMNS mixing matrix $U = (V_{ij})$ defined by

$$L = -\frac{g}{\sqrt{2}} \bar{E}_L \gamma^\mu U \nu_L W^-_\mu + h.c. \tag{3}$$

where $E_L = (e, \mu, \tau, ...)^T_L$, $\nu_L = (\nu_1, \nu_2, \nu_3, ...)^T_L$, and U is a $n \times n$ unitary matrix for n generations.

For SM3, U can be parameterized as[1]

$$U = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix} , \tag{4}$$

where $c_{ij} = \cos\theta_{ij}$ and $s_{ij} = \sin\theta_{ij}$ with θ_{ij} being rotation angles and δ being the CP violating phase.

The charged lepton masses have been measured with great precision. But the neutrino masses are not. The absolute values for neutrino mass scale, although not known, are constrained to be small ($m_\nu < 2.3$ eV by tritium beta decay experiment[20], and $\sum m_i < 0.61$ eV by cosmological observations[21]), and the mass differences are known from neutrino oscillation data. The mixing angles are also constrained by various experimental data in particular from neutrino oscillation data. We list these constraints on neutrino mixing and masses in the following

$$\begin{aligned}&\sin^2(2\theta_{12}) = 0.87 \pm 0.23 \text{ [22]},\ \sin^2(2\theta_{23}) > 0.92 \text{ [23]},\ \sin^2(2\theta_{13}) < 0.15\ \ \mathrm{CL} = 90\%\text{[24]},\\ &\Delta m^2_{21} = (7.59 \pm 0.20) \times 10^{-5} \text{ [22]},\ |\Delta m^2_{31}| = (2.43 \pm 0.13) \times 10^{-3}\mathrm{eV}^2\text{[25]},\end{aligned} \qquad (5)$$

where $\Delta m^2_{ij} = m^2_i - m^2_j$, and $m_i (i = 1\text{–}3)$ are the mass eigenvalues of neutrinos. Recently T2K has obtained new evidence[26] showing that the angle θ_{13} may indeed be non-zero with the 90% c.l. allowed region $0.03(0.04) \sim 0.28(0.34)$ for $\sin^2(2\theta_{13})$ for normal (inverted) neutrino mass hierarchy.

In this model FCNC processes do not occur at the tree level, but it can happen at one loop level. Due to GIM mechanism of the model for lepton sector, amplitudes for any leptonic FCNC processes with charged leptons are proportional to $\Delta m^2_{ij}/m^2_W$. Since squared differences of neutrino masses are constrained as in above, all FCNC processes involve charged leptons including $\mu - e$ conversion, are very small which are well below experimental sensitivity. To have observable FCNC effects, further extensions are needed. A simple way which can overcome the problem of small $\Delta m^2_{ij}/m^2_W$ ratio is to have a heavy neutrino in the model. This can be achieved for a model with four generations (SM4).

The existence of a fourth generation of quarks and leptons is not ruled out although there are severe constraints. The heavy neutrino must be heavier than $m_Z/2$ such that the precisely measured Z decay width would not be upset. The LEP II data constraint the mass to be even larger with $m_{\nu_4} > 90.3$GeV at 95%CL [27]. The constraint from electroweak precision data can also be evaded by imposing appropriate mass splitting between fourth generations[28]. Perturbative unitarity bound on a heavy fourth generation Yukawa coupling constant has been considered[29]. Critical masses determined by perturbativity for charged leptons and neutrinos are about 1.2 TeV[29]. The fourth generation neutrinos, if exists, with a large mass in the range about 100 GeV to the unitarity bound are not ruled out. With the addition of the fourth generation, the PMNS matrix U will become a 4×4 unitary matrix. If mixing matrix elements in V_{i4} are not extremely small, larger FCNC effects can be generated at one loop level. From the neutrino oscillation data, the constraints on the mixing of the fourth generation with the first three light neutrinos are indeed allowed to be not extremely small as the large error bars in eq.(5) indicate. There is a chance for large FCNC effects in the lepton sector.

The strength of muonic FCNC processes is governed by powers of $\lambda_{\mu e} = V^*_{\mu 4} V_{e4}$. Loop induced FCNC interactions relevant to $\mu - e$ conversion can be obtained by standard loop calculations. We present the one loop effective Lagrangian in two terms in the following, in the limit of neglecting terms suppressed by light neutrino mass squared divided by the W mass squared,

$$\begin{aligned}L(\mu \to e\gamma) &= -\frac{4G_F}{\sqrt{2}}\frac{e}{32\pi^2}\lambda_{\mu e} G_2(x_4)\bar{e}\sigma^{\mu\nu}(m_\mu R + m_e L)\mu F_{\mu\nu}\ ,\\ L(\mu \to e + q\bar{q}) &= -\frac{G_F}{\sqrt{2}}\frac{e^2}{4\pi^2}\lambda_{\mu e}\left[V_u(x_4)\bar{u}\gamma_\mu u + V_d(x_4)\bar{d}\gamma_\mu d\right.\\ &\qquad \left.+A_u(x_4)\bar{u}\gamma_\mu\gamma_5 u + A_d(x_4)\bar{d}\gamma_\mu\gamma_5 d\right]\bar{e}\gamma^\mu L\mu\ ,\end{aligned} \qquad (6)$$

where $\sigma_{\mu\nu} = i[\gamma_\mu, \gamma_\nu]/2$, $R(L) = (1 \pm \gamma_5)/2$, $x_4 = m^2_{\nu_4}/m^2_W$, and

$$\begin{aligned}
V_q(x) &= -Q^q G_1(x) + \frac{1}{2s^2_W}(I^q_3 - Q^q s^2_W) G_Z(x) - \frac{1}{4s^2_W} G^q_B(x) \; , \\
A_q(x) &= -\frac{1}{s^2_W} I_3 G_Z(x) + \frac{1}{4s^2_W} G^q_B(x) \; , \\
G_1(x) &= \frac{x(12 + x - 7x^2)}{12(x-1)^3} - \frac{x^2(12 - 10x + x^2)}{6(x-1)^4} \ln x \; , \\
G_2(x) &= \frac{x(1 - 5x - 2x^2)}{4(x-1)^3} + \frac{3x^3}{2(x-1)^4} \ln x \; , \\
G_Z(x) &= \frac{x(x^2 - 7x + 6)}{4(x-1)^2} + \frac{x(2+3x)}{4(x-1)^2} \ln x \; , \\
G_B(x) &= \frac{x}{x-1} - \frac{x}{(x-1)^2} \ln x \; , \quad G^u_B(x) = 4G_B(x) \; , \quad G^d_B(x) = G_B(x) \; . \qquad (7)
\end{aligned}$$

In the above, Q^q is the electric charge of the quark q.

We also present the effective Lagrangian for $\mu \to e\bar{e}e$ in the following which will be used when we compare constraints on parameters,

$$\begin{aligned}
L(\mu \to e\bar{e}e) \; &= \; -\frac{G_F}{\sqrt{2}} \frac{e^2}{4\pi^2} \lambda_{\mu e} \Big[G_2(x_4)\, \bar{e}\gamma_\mu e \, \frac{q_\nu}{q^2} \, \bar{e} i\sigma^{\mu\nu} (m_\mu R + m_e L)\mu \\
&+ \; \bar{e}\gamma^\mu \left(a_L(x_4) L + a_R(x_4) R \right) e \, \bar{e}\gamma_\mu L \mu \Big] \; . \qquad (8)
\end{aligned}$$

where

$$a_L(x) = G_1(x) + \frac{1}{s^2_W}\Big(-\frac{1}{2} + s^2_W\Big) G_Z(x) - \frac{1}{2s^2_W} G_B(x) \; , \quad a_R(x) = G_1(x) + G_Z(x) \; . \qquad (9)$$

The term $L(\mu \to e\gamma)$ is generated by the electromagnetic penguin. The loop generates the function $G_2(x)$ for dipole operator. For the terms $L(\mu \to e + q\bar{q})$ and $L(\mu \to e\bar{e}e)$, there are several contributions. Connecting the photon in the dipole operator, this generates the terms proportional to $G_2(x)$. The electromagnetic penguin also generates a charge radius term. With the photon connected to a quark or an electron, the terms proportional to $G_1(x)$ are generated. Replacing the photon by a Z boson, terms proportional to $G_Z(x)$ are generated. Finally, the box diagram produce the terms proportional to $G_B(x)$. We note that in the large x limit the function $G_Z(x)$ linearly increases, while others are not. The results above agree with those in Ref.[18].

III. $\mu \to e$ CONVERSION CONSTRAINTS ON MODEL PARAMETERS

To obtain $\mu \to e$ conversion rates from the FCNC interaction discussed in the previous section, one needs to convert quarks into hadrons which depend on hadronic matrix element calculations. Theoretical efforts have been made by several group to calculated these matrix elements[6–8]. We will use the results in Ref.[8] for a consistent calculation. In this framework there are several quark level contributions which are parameterized as the following effective Lagrangian

$$\begin{aligned}
L_{eff} &= -\frac{4G_F}{\sqrt{2}}\left[m_\mu \bar{e}\sigma^{\mu\nu}(A_R R + A_L L)\mu F_{\mu\nu} + h.c.\right] \\
&- \frac{G_F}{\sqrt{2}}\left[\bar{e}(g_{LS(q)}R + g_{RS(q)}L)\mu\, \bar{q}q + \bar{e}(g_{LP(q)}R + g_{RP(q)}L)\mu\, \bar{q}\gamma_5 q + h.c.\right] \\
&- \frac{G_F}{\sqrt{2}}\left[\bar{e}(g_{LV(q)}\gamma^\mu L + g_{RV(q)}\gamma^\mu R)\mu\, \bar{q}\gamma_\mu q + \bar{e}(g_{LA(q)}\gamma^\mu L + g_{RA(q)}\gamma^\mu R)\mu\, \bar{q}\gamma_\mu\gamma_5 q + h.c.\right] \\
&- \frac{G_F}{\sqrt{2}}\left[\frac{1}{2}\bar{e}(g_{LT(q)}\sigma^{\mu\nu}R + g_{RT(q)}\sigma^{\mu\nu}L)\mu\, \bar{q}\sigma_{\mu\nu}q + h.c.\right] . \qquad (10)
\end{aligned}$$

In SM4, at the one loop level, we have, $g_{(L,R)(S,P,T)(q)} = 0$, $g_{RV(q)} = 0$, and

$$A_R = \frac{e}{32\pi^2}\lambda_{\mu e}G_2(x_4)\ , \quad A_L = \frac{m_e}{m_\mu}A_R\ , \quad g_{LV(q)} = \frac{e^2}{4\pi^2}\lambda_{\mu e}V_q\ . \qquad (11)$$

The contribution from A_L can be neglected compared with that from A_R. The contribution from $g_{L(R)A}$ terms proportional to A_q in eq.(6) is suppressed because the fraction of the coherent process is generally larger than that of the incoherent one approximately by a factor of the mass number of the target nuclei[8].

The quantity $B^A_{\mu\to e}$ measuring the leptonic FCNC effect in $\mu \to e$ conversion to the leading order in SM4 is proportional to

$$|A_R D + \tilde{g}^{(p)}_{LV}V^{(p)} + \tilde{g}^{(n)}_{LV}V^{(n)}|^2\ , \qquad (12)$$

where

$$\tilde{g}^{(p)}_{LV} = 2g_{LV(u)} + g_{LV(d)}\ , \quad \tilde{g}^{(n)}_{LV} = g_{LV(u)} + 2g_{LV(d)}\ . \qquad (13)$$

Combining these, we obtain

$$\frac{B^A_{\mu\to e}}{B(\mu\to e\gamma)} = R^0_{\mu\to e}(A)\left|1 + \frac{\tilde{g}^{(p)}_{LV}V^{(p)}(A)}{A_R D(A)} + \frac{\tilde{g}^{(n)}_{LV}V^{(n)}(A)}{A_R D(A)}\right|^2\ , \qquad (14)$$

where

$$R^0_{\mu\to e}(A) = \frac{G_F^2 m_\mu^5}{192\pi^2\Gamma^A_{capt}}|D(A)|^2\ . \qquad (15)$$

The relevant parameters are listed in Table I, which are evaluated using method I in Ref.[8].

In Fig.1 we show constraints on $\lambda_{\mu e}$ as a function of the fourth generation neutrino mass m_{ν_4} using experimental upper limits on $\mu - e$ conversion for Au, S, Ti and Pb nuclei. The most stringent constraint comes from Au. We see that $\lambda_{\mu e}$ is constrained to be less than 1.6×10^{-5} for m_{ν_i} larger than 100 GeV. Such a small value for $\lambda_{\mu e}$ is well within the error bars allowed ranges from neutrino oscillation data. To see whether $\mu - e$ conversion provides the strongest constrains on the model parameters, one needs to check with other leptonic FCNC processes. In the next section we compare the $\mu - e$ conversion constraints with those obtained from other two well known leptonic FCNC processes $\mu \to e\gamma$ and $\mu \to e\bar{e}e$.

A	D(A)	$V^{(p)}$(A)	$V^{(n))}$(A)	$R^0_{\mu\to e}$(A)

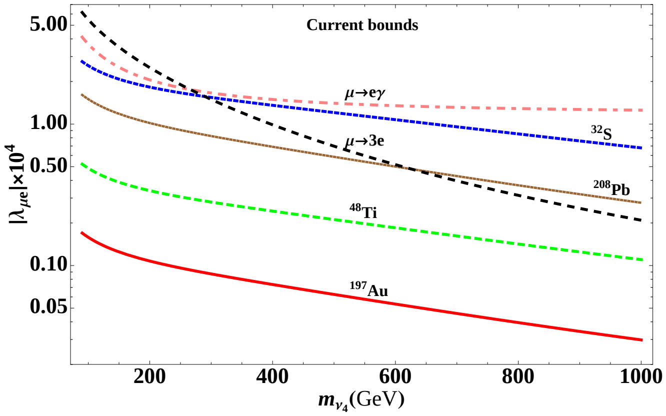

FIG. 1: Constraints on $|\lambda_{\mu e}|$ as a function of neutrino mass m_{ν_4} from current experimental bounds on $\mu - e$ conversion, $\mu \to e\gamma$ and $\mu \to e\bar{e}e$.

IV. COMPARISONS WITH CONSTRAINTS FROM $\mu \to e\gamma$ AND $\mu \to e\bar{e}e$

$\mu \to e\gamma$ and $\mu \to e\bar{e}e$ are two well known processes which provide stringent constraints on leptonic FCNC interactions. Experimental measurement for $\mu \to e\gamma$ is not an easy task. Nevertheless, several groups have made efforts in obtaining limit on this decay. No positive result on the observation of this decay has been reported. The best upper bound at the 90%CL, set more than 10 years ago, is $B(\mu \to e\gamma) < 1.2 \times 10^{-11}$[30]. Recently MEG collaboration has reported their preliminary result on the upper limit with $B(\mu \to e\gamma) < 1.5 \times 10^{-11}$ based on their 2009 physics data collection[31]. This bound is slightly weaker than the best upper bound. It is, however, intriguing to note that they did have a few events well separated from backgrounds in their photon and electron energy cuts plot. However, due to low statistics, no positive claims can be made. MEG experiment has potential to improve the sensitivity by two orders of magnitudes, 10^{-13}[32]. Experimental studies of $\mu \to e\bar{e}e$ has put a stringent limit on the branching ratio. The current best limit is $B(\mu \to e\bar{e}e) < 1.0 \times 10^{-12}$[33].

Using the effective Lagrangian $L(\mu \to e\gamma)$ in eq. (6), one can obtain the branching ratio $B(\mu \to e\gamma) = \Gamma(\mu \to e\gamma)/\Gamma(\mu \to e\nu\bar{\nu})$. Neglecting m_e, one obtains

$$B(\mu \to e\gamma) = 384\pi^2(|A_L|^2 + |A_R|^2) \ , \qquad (16)$$

where $A_{R,L}$ are defined in eq.(11). If the mass m_e is kept, one should divide, in the above expression,

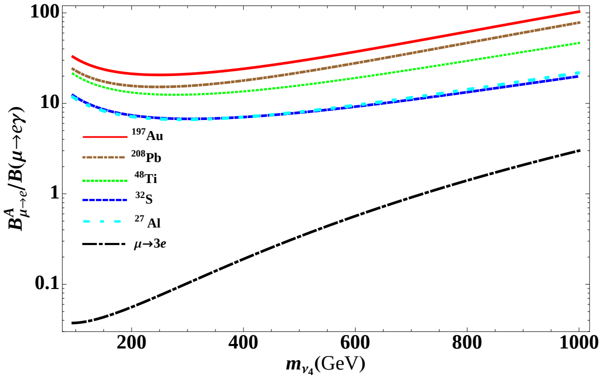

FIG. 2: Ratios of $B^A_{(\mu-e)}/B(\mu \to e\gamma)$ and $B(\mu \to e\bar{e}e)/B(\mu \to e\gamma)$ as functions of m_{ν_4}.

a phase factor $I(x) = 1-8x+8x^3-x^4-12x^2\ln x$ with $x = m_e^2/m_\mu^2$. Radiative corrections from QED also modify the above expression by dividing a factor $1+\delta_{QED}$ with $\delta_{QED} = (\alpha/2\pi)(25/4-\pi^2)$.

The branching ratio for $\mu \to e\bar{e}e$ can be deduced from $L(\mu \to e\bar{e}e)$ in eq.(8). We have

$$\begin{aligned} B(\mu \to e\bar{e}e) &= \frac{\alpha^2}{16\pi^2}|\lambda_{\mu e}|^2 \left[a_R^2(x_4) + 2a_L^2(x_4)\right. \\ &- \left. 4G_2(x_4)(a_R(x_4)+2a_L(x_4)) + 4G_2^2(x_4)\Big(4\ln\frac{m_\mu}{m_e} - \frac{11}{2}\Big)\right] . \end{aligned} \tag{17}$$

The constraints on the parameter $\lambda_{\mu e}$ as functions of m_{ν_4} for bounds from $\mu \to e\gamma$ and $\mu \to e\bar{e}e$ are also shown in Fig.1. The constraint obtained from $\mu \to e\bar{e}e$ is weaker for neutrino mass $m_{\nu 4}$ less than 255 GeV than that from $\mu \to e\gamma$, but becomes stronger for larger mass for the current experimental bounds. This property is mainly caused by Z-penguin contributions. However, the constraints from $\mu - e$ conversion on Ti and Au are better than those from $\mu \to e\gamma$ and $\mu \to e\bar{e}e$. The best constraint comes from $\mu - e$ conversion on Au nuclei.

In Fig.2 we show the ratios of $B^A_{(\mu-e)}/B(\mu \to e\gamma)$ and $B(\mu \to e\bar{e}e)/B(\mu \to e\gamma)$ as functions of m_{ν_4}. For a given fourth generation neutrino mass, the ratios are fixed independent the value of $\lambda_{\mu e}$. We see that in the region with m_{ν_4} larger than 100 GeV, the ratios for $\mu - e$ conversion of various nuclei are larger than one implying that if the experimental values for the $\mu - e$ conversion rate and $\mu \to e\gamma$ branching ratio are similar, the constraint from $\mu - e$ conversion will give stronger constraints on the parameter $\lambda_{\mu e}$ which explains the fact that the current experimental bounds on $\mu - e$ conversion from Ti and Au provide stronger constraints. When m_{ν_4} becomes larger ratios become larger due to the fact that the Z penguin whose contribution increases with $m^2_{\nu_4}$ for $\mu - e$ conversion and $\mu \to e\bar{e}e$, but $\mu \to e\gamma$ increases only logarithmically in large m_{ν_4} limit.

If one takes the well separated events of the MEG data as $\mu \to e\gamma$ events, the branching ratio implied would be of order 10^{-12}, we will take an assumed branching ratio of 3×10^{-12} to show the implication on the parameters required to produce it. We show the results in Fig.3. We see that such a possibility is ruled out by $\mu - e$ conversion on Au nuclei in this model (see also Fig.1). In Fig.3, we also plot possible constraints on parameters using several projected experimental sensitivities on the $\mu - e$ conversion, $\mu \to e\gamma$ and $\mu \to e\bar{e}e$. We see that the improved experiment MEG on $\mu \to e\gamma$ and MuSIC[34] on $\mu \to e\bar{e}e$ can obtain better constraints than the current Au bound.

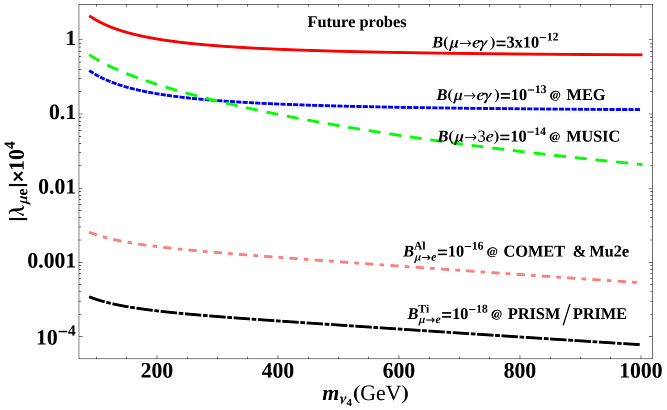

FIG. 3: Constraints on 4th-generation mixing coupling $|\lambda_{\mu e}|$ as a function of neutrino mass m_{ν_4} from several future experimental sensitivities on $\mu - e$ conversion, $\mu \to e\gamma$ and $\mu \to e\bar{e}e$.

Future experiments Mu2E[35]/COMET[36] and PRISM[37] for $\mu - e$ conversion using Al and Ti, respectively, can obtain much better constraints.

V. CONCLUSIONS

We have studied $\mu - e$ conversion in the SM with four generations. A large mass m_{ν_4} for the fourth generation neutrino can enhance the conversion rate by orders of magnitude. We have compared constraints obtained from $\mu - e$ conversion using experimental bounds on various nuclei with those from $\mu \to e\gamma$ and $\mu \to e\bar{e}e$. We found that the current bound from $\mu - e$ conversion with Au puts the most stringent constraint in this model. The relevant flavor changing parameter $\lambda_{\mu e} = V^*_{\mu 4}V_{e4}$ is constrained to be less than 1.6×10^{-5} for m_{ν_4} larger than 100 GeV. The goal of MEG experiment is to have a sensitivity of 10^{-13} for $B(\mu \to e\gamma)$, which can compete that of $\mu - e$ conversion in Au in this model. Therefore, the model prediction can be tested by combining these coming data. There are several proposed experiment for $\mu - e$ conversion, Mu2E[35], COMET[36] and PRISM[37], which will tell us detailed information of lepton flavor mixing. In addition, successful running and energy upgrade of Large Hadron Collider will search for sequential fourth generation fermions. The fourth generation model will be explored directly and indirectly by future experiments in great detail.
